Dynamic Adhoc On Demand Distance Vector Routing Protocol Designed for MANET: Comparative Survey

Rahul Mukherjee
Assistant Professor, Electronics & Telecommunication Engineering Department, Rungta College of Engineering & Technology (RCET),

Abstract

A Mobile Ad-hoc Network (MANET) is an assembly of wireless mobile nodes forming a temporary network without using any centralized access point, infrastructure, or centralized administration. Data transmission between two nodes in MANET’s may requires multiple hops as the node’s transmission range is limited. Mobility of the different nodes makes the situation even more complicated. Multiple routing protocols especially for these conditions have been developed during the last few years, to find optimized routes from a source to some destination.

Keywords - MANET, AODV, DATA

1. Introduction

An ad-hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any standalone infrastructure or centralized administration. Mobile Ad-hoc networks are self-organizing and self-configuring multi-hop wireless networks where, the structure of the network changes dynamically. Reactive protocols seek to set up routes on-demand. If a node wants to initiate communication with a node to which it has no route, the routing protocol will try to establish such a route [17]

AODV is a reactive routing protocol instead of proactive. It minimizes the number of broadcasts by creating routes based on demand, which is not the case for DSDV. When any source node wants to send a packet to a destination, it broadcasts a route request (RREQ) packet. The neighboring nodes in turn broadcast the packet to their neighbors and the process continues until the packet reaches the destination. During the process of forwarding the route request, intermediate nodes record the address of the neighbor from which the first copy of the broadcast packet is received. This record is stored in their route tables, which helps for establishing a reverse path. [18]

3. Objectives

Research is a planning based work. All works related to researching are generally a planning and trying to achieve a specific goal. In this research work, there are some planned objectives that we will try to achieve –

1. Reduce latency time in route finding.
2. Less Route discovery packet flooding.
3. Overcome collisions between route requests propagated by neighboring nodes.
4. Develop a resilient, adaptive and reactive routing protocol.

4. Sun et al. [4]

Behaviors of critical objects are manually abstracted and crafted as security specifications. The IDS presented in this paper was built on a distributed network monitor architecture that traces AODV request-reply flows.

5. Rendong Bai et al. [5]

Presented a light-weight hierarchical routing model, called Way Point Routing (WPR), in which a number of intermediate nodes on a route are selected as waypoints and the route is divided into segments by the waypoints. The advantage of this model is that when a node on the route moves out or fails, instead of discarding the whole original route and discovering a new route from the source to the destination, only the two waypoint nodes of the broken segment have to find a new segment.

A cross-layer based stable routing protocol for ad-hoc networks, which enhances support for QoS. The protocol uses only local information.

But this scheme was designed to combine explicitly with QoS routing, thereby incorporating...
The main goal of an ad-hoc network routing protocol is to establish a correct and efficient route between a pair of mobile nodes so that messages delivered within the active route timeout interval. So Routing Protocols are too important for networking. So if we are able to prepare a routing protocol having above features, then it’s a use full research work.

4. Noteworthy Contribution

The progress of a world is based on research work in different fields. Research is helpful for developing knowledge and also searches new knowledge and played an important role to give progress for that new search. Proposed research work is also based on above points. Reactive protocols to seek to set up routes on-demand. If a node wants to initiate communication with a node to which it has no route, the routing protocol will try to establish such a route. Reactive routing protocol is truly based on source routing whereby all the routing information is maintained (continually updated) at mobile nodes. It has only two major phases, which are Route Discovery and Route Maintenance. So we will try to achieve these two phases in advance features. The importance to this research work is to reduce latency time in route finding, and Less Route discovery packet flooding. And also overcome collisions between route requests propagated by neighboring nodes.

Proposed Work

This research work will present a solution to reduce latency time in route finding. Generally its typical process to find the shortest path for sending messages, and receiving acknowledgement. So we will use reactive routing protocol for this and Ad-hoc On-Demand distance vector (AODV) finds a route on demand by flooding the network with Route Request packets.

Research Methodology

The main goal of this research is to analysis and designs a re-silient, adoptive and responsive routing protocol. So that improve performance of responsive routing protocols compared to last decade. Hence we will use analysis method for getting demerits of reactive routing protocol and study the current status. We will get data from different sources through survey and present a new thought that gives a correct way of our research.
Primary sources will questionnaire and interview whereas secondary sources will research paper and journals. For this, research works to get actual situation, we will use practical work also for which we will be able to find or design new solution or algorithm. For this research work we will mainly use Ad-hoc on demand distance vector (AODV).

9. Ping XU et. al [9] Algorithm can reduce the delay of the route discover, enhance the stability of the path so as to improve the overall performance of the standard AODV protocol.

10. Lawal Bello et. al [10] Increase performance of AODV and DSR routing protocols. This performance comparison was aimed to maximize throughput in a large capacity network while minimizing end-to-end delay in the presence of increased ambient noise level. But it will be proper modeling of terrain effect prior to implementation to mitigate the effect of noise on received signal strength of the packet in a multi-hop network.

11. Tao Yang et. al [11] Presented simulation results of WSN for different cases of WSN. they used the packet loss, transport loss and routing loss metrics to measure the performance. But It can be increase the number of mobile sensor nodes and can consider the different topologies and also consider the case of other routing protocols and MAC topology.

12. Sridhar Subramanian [12] Designed a trust based reliable protocol TBRAODV. Trust level values for each node are calculated to identify the misbehaving nodes during routing. If node is misbehaving then it leads to an alternate path selection for further reliable routing. This trust based routing mechanism has proved to be increasing the performance of the proposed TBRAODV protocol. But The same scheme can also be implemented on other MANET routing protocols and also implement some techniques for authenticating the packet and the node which take part in routing.
and also shows good improvement of Qos parameters like PDR and delay.

Discussed knowledge added MA for minimum energy broadcast problem. MA actively aims on improving solution and is explicitly concerned in exploiting all available knowledge about the problem. MA will use.

Simulation results show that MA reduces the execution time to a large amount when compared to existing algorithms. The results validate the effectiveness and efficiency of MA to this problem.

Considered wireless sensor network design under resource restrictions. This research paper developed mathematical models for network design by simultaneously considering multiple periods and distance and energy limits. In this computation experiments demonstrate the usefulness of the presented model.

Propose a neighborhood connectivity based trust scheme that can detect the single and colluded attackers during route discovery and quarantine them. It can increase more robust and prevention system.
can work. Even the internal attackers cannot get any benefit to launch the active black hole attacks.

Table:

| Proposed a novel reactive routing protocol called iAODV that was derived from AODV protocol. | But this IF based route discovery process can also apply on DSR that can be more use full. |
| Andrea Gorrieri et. al [16] | This protocol used in its route discovery phase with the probabilistic forwarding mechanism denoted as IF. by the use of IF protocol the number of control messages is effectively reduced. |
